

Intermediate Code & Local Optimizations

Lecture 14

Prof. Aiken CS 143 Lecture 14

1

Lecture Outline

- Intermediate code
- Local optimizations
- Next time: global optimizations

Prof. Aiken CS 143 Lecture 14

2

Code Generation Summary

- We have discussed
 - Runtime organization
 - Simple stack machine code generation
 - Improvements to stack machine code generation
- Our compiler maps AST to assembly language
 - And does not perform optimizations

Prof. Aiken CS 143 Lecture 14

3

Optimization

- Optimization is our last compiler phase
- Most complexity in modern compilers is in the optimizer
 - Also by far the largest phase
- First, we need to discuss intermediate languages

Prof. Aiken CS 143 Lecture 14

4

Why Intermediate Languages?

- When should we perform optimizations?
 - On AST
 - **Pro:** Machine independent
 - **Con:** Too high level
 - On assembly language
 - **Pro:** Exposes optimization opportunities
 - **Con:** Machine dependent
 - **Con:** Must reimplement optimizations when retargeting
 - On an intermediate language
 - **Pro:** Machine independent
 - **Pro:** Exposes optimization opportunities

Prof. Aiken CS 143 Lecture 14

5

Intermediate Languages

- Intermediate language = high-level assembly
 - Uses register names, but has an unlimited number
 - Uses control structures like assembly language
 - Uses opcodes but some are higher level
 - E.g., **push** translates to several assembly instructions
 - Most opcodes correspond directly to assembly opcodes

Prof. Aiken CS 143 Lecture 14

6

Three-Address Intermediate Code

- Each instruction is of the form

$x := y \text{ op } z$
 $x := \text{op } y$

- y and z are registers or constants
- Common form of intermediate code

- The expression $x + y * z$ is translated

$t_1 := y * z$
 $t_2 := x + t_1$

- Each subexpression has a "name"

Prof. Aiken CS 143 Lecture 14

7

Generating Intermediate Code

- Similar to assembly code generation
- But use any number of IL registers to hold intermediate results

Prof. Aiken CS 143 Lecture 14

8

Generating Intermediate Code (Cont.)

- $\text{igen}(e, t)$ function generates code to compute the value of e in register t

- Example:

$\text{igen}(e_1 + e_2, t) =$
 $\text{igen}(e_1, t_1) \quad (t_1 \text{ is a fresh register})$
 $\text{igen}(e_2, t_2) \quad (t_2 \text{ is a fresh register})$
 $t := t_1 + t_2$

- Unlimited number of registers
 \Rightarrow simple code generation

Prof. Aiken CS 143 Lecture 14

9

Intermediate Code Notes

- You should be able to use intermediate code
 - At the level discussed in lecture
- You are not expected to know how to generate intermediate code
 - Because we won't discuss it
 - But really just a variation on code generation . . .

Prof. Aiken CS 143 Lecture 14

10

An Intermediate Language

$P \rightarrow SP \mid \epsilon$
 $S \rightarrow \text{id} := \text{id op id}$
 $\mid \text{id} := \text{op id}$
 $\mid \text{id} := \text{id}$
 $\mid \text{push id}$
 $\mid \text{id} := \text{pop}$
 $\mid \text{if id relop id goto L}$
 $\mid \text{L:}$
 $\mid \text{jump L}$

- id's are register names
- Constants can replace id's
- Typical operators: +, -, *

Prof. Aiken CS 143 Lecture 14

11

Definition. Basic Blocks

- A **basic block** is a maximal sequence of instructions with:
 - no labels (except at the first instruction), and
 - no jumps (except in the last instruction)
- Idea:
 - Cannot jump into a basic block (except at beginning)
 - Cannot jump out of a basic block (except at end)
 - A basic block is a single-entry, single-exit, straight-line code segment

Prof. Aiken CS 143 Lecture 14

12

Basic Block Example

- Consider the basic block
 1. L:
 2. $t := 2 * x$
 3. $w := t + x$
 4. if $w > 0$ goto L'
- (3) executes only after (2)
 - We can change (3) to $w := 3 * x$
 - Can we eliminate (2) as well?

Prof. Aiken CS 143 Lecture 14

13

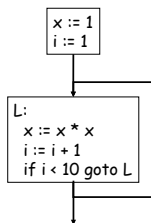

Definition. Control-Flow Graphs

- A control-flow graph is a directed graph with
 - Basic blocks as nodes
 - An edge from block A to block B if the execution can pass from the last instruction in A to the first instruction in B
 - E.g., the last instruction in A is `jump LB`
 - E.g., execution can fall-through from block A to block B

Prof. Aiken CS 143 Lecture 14

14

Example of Control-Flow Graphs

- The body of a method (or procedure) can be represented as a control-flow graph
- There is one initial node
- All "return" nodes are terminal

Prof. Aiken CS 143 Lecture 14

15

Optimization Overview

- Optimization seeks to improve a program's resource utilization
 - Execution time (most often)
 - Code size
 - Network messages sent, etc.
- Optimization should not alter what the program computes
 - The answer must still be the same

Prof. Aiken CS 143 Lecture 14

16

A Classification of Optimizations

- For languages like C and Cool there are three granularities of optimizations
 1. Local optimizations
 - Apply to a basic block in isolation
 2. Global optimizations
 - Apply to a control-flow graph (method body) in isolation
 3. Inter-procedural optimizations
 - Apply across method boundaries
- Most compilers do (1), many do (2), few do (3)

Prof. Aiken CS 143 Lecture 14

17

Cost of Optimizations

- In practice, a conscious decision is made not to implement the fanciest optimization known
- Why?
 - Some optimizations are hard to implement
 - Some optimizations are costly in compilation time
 - Some optimizations have low benefit
 - Many fancy optimizations are all three!
- Goal: Maximum benefit for minimum cost

Prof. Aiken CS 143 Lecture 14

18

Local Optimizations

- The simplest form of optimizations
- No need to analyze the whole procedure body
 - Just the basic block in question
- Example: algebraic simplification

Prof. Aiken CS 143 Lecture 14

19

Algebraic Simplification

- Some statements can be deleted
 - $x := x + 0$
 - $x := x * 1$
- Some statements can be simplified
 - $x := x * 0 \Rightarrow x := 0$
 - $y := y ** 2 \Rightarrow y := y * y$
 - $x := x * 8 \Rightarrow x := x \ll 3$
 - $x := x * 15 \Rightarrow t := x \ll 4; x := t - x$
(on some machines \ll is faster than $*$; but not on all!)

Prof. Aiken CS 143 Lecture 14

20

Constant Folding

- Operations on constants can be computed at compile time
 - If there is a statement $x := y \text{ op } z$
 - And y and z are constants
 - Then $y \text{ op } z$ can be computed at compile time
- Example: $x := 2 + 2 \Rightarrow x := 4$
- Example: if $2 < 0$ jump L can be deleted
- When might constant folding be dangerous?

Prof. Aiken CS 143 Lecture 14

21

Flow of Control Optimizations

- Eliminate unreachable basic blocks:
 - Code that is unreachable from the initial block
 - E.g., basic blocks that are not the target of any jump or "fall through" from a conditional
- Why would such basic blocks occur?
- Removing unreachable code makes the program smaller
 - And sometimes also faster
 - Due to memory cache effects (increased spatial locality)

Prof. Aiken CS 143 Lecture 14

22

Single Assignment Form

- Some optimizations are simplified if each register occurs only once on the left-hand side of an assignment
- Rewrite intermediate code in *single assignment* form
 - $x := z + y \quad b := z + y$
 - $a := x \quad a := b$
 - $x := 2 * x \quad x := 2 * b$
 - (b is a fresh register)
 - More complicated in general, due to loops

Prof. Aiken CS 143 Lecture 14

23

Common Subexpression Elimination

- If
 - Basic block is in single assignment form
 - A definition $x :=$ is the first use of x in a block
- Then
 - When two assignments have the same rhs, they compute the same value
- Example:
 - $x := y + z \quad x := y + z$
 - $\dots \quad \dots$
 - $w := y + z \quad w := x$
 - (the values of x , y , and z do not change in the \dots code)

Prof. Aiken CS 143 Lecture 14

24

Copy Propagation

- If $w := x$ appears in a block, replace subsequent uses of w with uses of x
 - Assumes single assignment form
- Example:

$b := z + y$	\Rightarrow	$b := z + y$
$a := b$		$a := b$
$x := 2 * a$		$x := 2 * b$
- Only useful for enabling other optimizations
 - Constant folding
 - Dead code elimination

Prof. Aiken CS 143 Lecture 14

25

Copy Propagation and Constant Folding

- Example:

$a := 5$	\Rightarrow	$a := 5$
$x := 2 * a$		$x := 10$
$y := x + 6$		$y := 16$
$t := x * y$		$t := x \ll 4$

Prof. Aiken CS 143 Lecture 14

26

Copy Propagation and Dead Code Elimination

If

$w := rhs$ appears in a basic block
 w does not appear anywhere else in the program

Then

the statement $w := rhs$ is dead and can be eliminated
- Dead = does not contribute to the program's result

Example: (a is not used anywhere else)

$x := z + y$	$b := z + y$	$b := z + y$
$a := x$	$\Rightarrow a := b$	$\Rightarrow x := 2 * b$
$x := 2 * a$		$x := 2 * b$

Prof. Aiken CS 143 Lecture 14

27

Applying Local Optimizations

- Each local optimization does little by itself
- Typically optimizations interact
 - Performing one optimization enables another
- Optimizing compilers repeat optimizations until no improvement is possible
 - The optimizer can also be stopped at any point to limit compilation time

Prof. Aiken CS 143 Lecture 14

28

An Example

- Initial code:
 $a := x ** 2$
 $b := 3$
 $c := x$
 $d := c * c$
 $e := b * 2$
 $f := a + d$
 $g := e * f$

Prof. Aiken CS 143 Lecture 14

29

An Example

- Algebraic optimization:
 $a := x ** 2$
 $b := 3$
 $c := x$
 $d := c * c$
 $e := b * 2$
 $f := a + d$
 $g := e * f$

Prof. Aiken CS 143 Lecture 14

30

An Example

- Algebraic optimization:

```
a := x * x
b := 3
c := x
d := c * c
e := b << 1
f := a + d
g := e * f
```

Prof. Aiken CS 143 Lecture 14

31

An Example

- Copy propagation:

```
a := x * x
b := 3
c := x
d := c * c
e := b << 1
f := a + d
g := e * f
```

Prof. Aiken CS 143 Lecture 14

32

An Example

- Copy propagation:

```
a := x * x
b := 3
c := x
d := x * x
e := 3 << 1
f := a + d
g := e * f
```

Prof. Aiken CS 143 Lecture 14

33

An Example

- Constant folding:

```
a := x * x
b := 3
c := x
d := x * x
e := 3 << 1
f := a + d
g := e * f
```

Prof. Aiken CS 143 Lecture 14

34

An Example

- Constant folding:

```
a := x * x
b := 3
c := x
d := x * x
e := 6
f := a + d
g := e * f
```

Prof. Aiken CS 143 Lecture 14

35

An Example

- Common subexpression elimination:

```
a := x * x
b := 3
c := x
d := x * x
e := 6
f := a + d
g := e * f
```

Prof. Aiken CS 143 Lecture 14

36

An Example

- Common subexpression elimination:

```
a := x * x
b := 3
c := x
d := a
e := 6
f := a + d
g := e * f
```

Prof. Aiken CS 143 Lecture 14

37

An Example

- Copy propagation:

```
a := x * x
b := 3
c := x
d := a
e := 6
f := a + d
g := e * f
```

Prof. Aiken CS 143 Lecture 14

38

An Example

- Copy propagation:

```
a := x * x
b := 3
c := x
d := a
e := 6
f := a + a
g := 6 * f
```

Prof. Aiken CS 143 Lecture 14

39

An Example

- Dead code elimination:

```
a := x * x
b := 3
c := x
d := a
e := 6
f := a + a
g := 6 * f
```

Prof. Aiken CS 143 Lecture 14

40

An Example

- Dead code elimination:

```
a := x * x
```

```
f := a + a
g := 6 * f
```

- This is the final form

Prof. Aiken CS 143 Lecture 14

41

Peephole Optimizations on Assembly Code

- These optimizations work on intermediate code
 - Target independent
 - But they can be applied on assembly language also
- Peephole optimization is effective for improving assembly code
 - The "peephole" is a short sequence of (usually contiguous) instructions
 - The optimizer replaces the sequence with another equivalent one (but faster)

Prof. Aiken CS 143 Lecture 14

42

Peephole Optimizations (Cont.)

- Write peephole optimizations as replacement rules

$i_1, \dots, i_n \rightarrow j_1, \dots, j_m$
where the rhs is the improved version of the lhs

- Example:

`move $a $b, move $b $a → move $a $b`

- Works if `move $b $a` is not the target of a jump

- Another example

`addiu $a $a i, addiu $a $a j → addiu $a $a i+j`

Prof. Aiken CS 143 Lecture 14

43

Peephole Optimizations (Cont.)

- Many (but not all) of the basic block optimizations can be cast as peephole optimizations

- Example: `addiu $a $b 0 → move $a $b`

- Example: `move $a $a →`

- These two together eliminate `addiu $a $a 0`

- As for local optimizations, peephole optimizations must be applied repeatedly for maximum effect

Prof. Aiken CS 143 Lecture 14

44

Local Optimizations: Notes

- Intermediate code is helpful for many optimizations
- Many simple optimizations can still be applied on assembly language
- “Program optimization” is grossly misnamed
 - Code produced by “optimizers” is not optimal in any reasonable sense
 - “Program improvement” is a more appropriate term
- Next time: global optimizations

Prof. Aiken CS 143 Lecture 14

45
